

CS 97SI: INTRODUCTION TO PROGRAMMING CONTESTS

Jaehyun Park

Today's Lecture: Combinatorial Games

- What are combinatorial games?
- Part 1
 - ▣ Simple Games
 - ▣ Minimax Algorithm
- Part 2
 - ▣ Nim Game
 - ▣ Grundy Numbers (Nimbers)
- Problem Discussion

Combinatorial Games

- Turn-based competitive multi-player games
- Can be a simple win-or-lose game, or can involve points
- Everyone has perfect information
- Each turn, the player changes the current “state” using a valid “move”
- At some states, there are no valid moves
 - ▣ The current player immediately wins or loses at these states

Combinatorial Game Example

- Settings: There are n stones in a pile. Two players take turns and remove 1 or 3 stones at a time. The one who takes the last stone wins. Find out the winner if both players play perfectly
- State space: Each state can be represented by the number of remaining stones in the pile
- Valid moves from state x : $x \rightarrow (x - 1)$ or $x \rightarrow (x - 3)$, as long as the resulting number is nonnegative
- State 0 is the losing state

Example (continued)

- No cycles in the state transitions
 - ▣ Can solve the problem bottom-up (DP!)
- A player wins if there is a way to force the opponent to lose
 - ▣ Conversely, we lose if there is no such a way
- State x is a winning state (W) if
 - ▣ $(x - 1)$ is a losing state,
 - ▣ OR $(x - 3)$ is a losing state
- Otherwise, state x is a losing state (L)

Example (continued)

- Let's see how the DP table looks like...

<i>n</i>	0	1	2	3	4	5	6	7
W/L	L	W	L	W	L	W	L	W

- See a pattern?
- Let's prove our conjecture

Example (continued)

- Conjecture: If n is odd, the first player wins. If n is even, the second player wins.
- Holds true for the base case $n = 0$
- In general,
 - ▣ If n is odd, we can remove one stone and give the opponent an even number of stones
 - ▣ If n is even, no matter what we choose, we have to give an odd number of stones to the opponent

More Complex Games

- Settings: a competitive zero-sum two-player game
 - ▣ Zero-sum: if the first player's score is x , then the other player gets $-x$
 - ▣ Each player tries to maximize his/her own score
 - ▣ Both players play perfectly
- Can be solved using a minimax algorithm

Minimax Algorithm

- Recursive algorithm that decides the best move for the current player at a given state
- Define $f(S)$ as the optimal score of the current player who starts at state S
- Let T_1, T_2, \dots, T_m be states can be reached from S using a single move
- Let T be the state that minimizes $f(T)$
- Then, $f(S) = -f(T)$
 - ▣ Intuition: minimizing the opponent's score maximizes my score

Memoization

- (Not “memorization” but “memoization”)
- A technique used to avoid repeated calculations in recursive functions
- High-level idea: take a note (memo) of the return value of a function call. When the function is called with the same argument again, return the stored result
- Each subproblem is solved at most once
 - ▣ Some may not be solved at all!

Recursive Function without Memoization

```
int fib(int n)
{
    if(n <= 1) return n;
    return fib(n - 1) + fib(n - 2);
}
```

□ How many times is `fib(1)` called?

Memoization using `std::map`

```
map<int, int> memo;
int fib(int n)
{
    if(memo.count(n)) return memo[n];
    if(n <= 1) return n;
    return memo[n] = fib(n - 1) + fib(n - 2);
}
```

□ How many times is `fib(1)` called?

Minimax Algorithm Pseudocode

- Given state S , want to compute $f(S)$
- If we know $f(S)$ already, return it
- Set return value $x := -\infty$
- For each valid next state T
 - ▣ Update return value $x := \max(x, -T)$
- Write a memo $f(S) = x$ and return x

Possible Extensions

- The game is not zero-sum
 - ▣ Each player wants to maximize his own score
 - ▣ Each player wants to maximize the difference between his score and the opponent's
- There are more than two players
- All of above can be solved using a similar idea

Nim Game

- Settings: There are n piles of stones. Two players take turns. Each player chooses a pile, and removes any number of stones from the pile. The one who takes the last stone wins. Find out the winner if both players play perfectly
- Can't really use DP if there are many piles, because the state space is huge

Nim Game Illustration

- Starts with heaps of 3, 4, 5 stones
 - ▣ We will call them heap A, heap B, and heap C
- Alice takes 2 stones from A: 1, 4, 5
- Bob takes 4 from C: 1, 4, 1
- Alice takes 4 from B: 1, 0, 1
- Bob takes 1 from A: 0, 0, 1
- Alice takes 1 from C and wins: 0, 0, 0

Solution to Nim

- Given heaps of size n_1, n_2, \dots, n_m
- The first player wins if and only if the *nim-sum* $n_1 \oplus n_2 \oplus \dots \oplus n_m$ is nonzero (\oplus is the bitwise XOR operator)
- Why?
 - ▣ If the nim-sum is zero, then whatever the current player does, the nim-sum of the next state is nonzero
 - ▣ If the nim-sum is nonzero, it is possible to force it to become zero (not obvious, but true)

Playing Multiple Games at Once

- Suppose that multiple games are played at the same time. At each turn, the player chooses a game and make a move. You lose if there is no possible move. We want to determine the winner

Figure from <http://sps.nus.edu.sg/~limchuwe/cgt/>

Grundy Numbers (Nimbers)

- For each game, we compute its *Grundy number*
- The first player wins if and only if the XOR of all the Grundy numbers is nonzero
 - ▣ For example, the Grundy number of a one-pile version of the nim game is equal to the number of stones in the pile (we will see this again later)
- Let's see how to compute the Grundy numbers for general games

Grundy Numbers

- Let S be a state, and T_1, T_2, \dots, T_m be states can be reached from S using a single move
- The Grundy number $g(S)$ of S is the smallest nonnegative integer that doesn't appear in $\{g(T_1), g(T_2), \dots, g(T_m)\}$
 - ▣ Note: the Grundy number of a losing state is 0
 - ▣ Note: I made up the notation $g(\cdot)$. Don't use it in other places

Grundy Numbers Example

- Consider a one-pile nim game
- $g(0) = 0$, because it is a losing state
- 0 is the only state reachable from state 1, so $g(1)$ is the smallest nonnegative integer not appearing in $\{g(0)\} = \{0\}$. Thus, $g(1) = 1$
- Similarly, $g(2) = 2$, $g(3) = 3$, and so on
- Grundy numbers for this game is then $g(n) = n$
 - ▣ That's how we got the nim-sum solution

Another Example

- Let's consider a variant of the game we considered before; only 1 or 2 stones can be removed at each turn
- Now we're going to play many copies of this game at the same time
- Grundy number table:

n	0	1	2	3	4	5	6	7
$g(n)$	0	1	2	0	1	2	0	1

Another Example (continued)

- Grundy number table:

n	0	1	2	3	4	5	6	7
$g(n)$	0	1	2	0	1	2	0	1

- Who wins if there are three piles of stones (2, 4, 5)?
- What if we start with (5, 11, 13, 16)?
- What if we start with (10^{100} , 10^{200})?

Tips for Solving Game Problems

- If the state space is small, use memoization
- If not, print out the result of the game for small test data and look for a pattern
 - ▣ This actually works really well!
- Try to convert the game into some nim-variant
- If multiple games are played at once, use Grundy numbers
